INSURANCE FRAUD DETECTION AND PREVENTION IN THE ERA OF BIG DATA

CURBING FRAUD BY APPLICATION OF ADVANCED
ANALYTICS ACROSS POLICY LIFECYCLE

DECISION POINT™
— by **WNS**

DECISIONPOINT™
— by WNS

Overview

Every year claims and underwriting fraud cost $80 billion and ~ $34 billion, specifically to Property and Casualty Industry (P&C). This indicates the inefficiency of current fraud detection techniques deployed by the insurers. The ability to analyze only a small portion of data is one of the main reasons for the under-performance of the existing fraud detection techniques, especially when it comes to detecting sophisticated fraud operations. Fraud management systems that leverage advanced analytics tools such as predictive modeling can greatly impact both the cost and success of fighting fraud, which in turn will positively impact the combined ratio and profitability.

With the growing complexity of fraud, insurers need to put in place forward-looking fraud detection techniques that efficiently analyze untapped data and help to minimize fraud loss. Insurers tend to collect voluminous amounts of Big Data in various forms (structured, semi-structured and unstructured) during the policy application, servicing and claims processes, which are seldom evaluated in fraud investigation operations. Combining analysis of Big Data along with the existing fraud detection techniques enable insurers to augment productivity of underwriting and claims processes and also maintain a competitive advantage.

To assess the impact and adoption of Big Data analytics on detecting and preventing insurance fraud, WNS DecisionPoint™ conducted a survey of the US P&C insurers. The study analyzes current fraud detection practices adopted by insurers at three stages of the policy life cycle: the underwriting stage, the claims handling stage, and the investigation stage. It highlights the evolution of fraud detection techniques from manual processes involving an expert-based approach, to automated techniques, to data-driven analytical models that offer more valuable insights to identify fraudulent activities.

Insurance fraud is one of the biggest crimes in the U.S., reporting payout of $80 billion every year, imposing heavy costs on insurers and its customers

DECISIONPOINT™
— by **WNS**

THE COST OF INSURANCE FRAUD

Insurance fraud is one of the biggest crimes in the U.S., reporting payout of $80 billion (for the entire insurance industry) every year, imposing heavy costs on insurers and its customers.

FRAUD AT POINT OF SALE

Point of sale (POS) fraud, also known as premium or underwriting fraud, takes place when the applicant purposely hides or distorts facts/information when obtaining insurance coverage. Fraud at the POS stage, which erodes 10 percent of insurance revenue[i], is increasing due to a rise in digital sales channels, which make it easy for individuals to reduce premiums by easily manipulating data, such as age, previous claims and zip code, among others. To make matters worse, pressure on carriers to increase revenues and higher customer switch ratio limits underwriters from scrutinizing all the applications in detail.

Workers' compensation (part of commercial line insurance) is most exposed to such fraud, where employers avoid premiums by reporting fewer employees or inappropriately classifying employees with high-risk jobs as holding lower-risk ones. About 10-20 percent of employers in the U.S. misclassify at least one worker as an independent contractor[ii]. Employers committing such fraud are higher in number in the Southern states, where around 30 percent of construction workers have been wrongly classified as independent contractors, amounting to annual losses of $400 million in Florida, $467 million in North Carolina, and $1.2 billion in Texas[ii].

FRAUD AT CLAIMS STAGE

According to the survey by FICO[1] on 'Insights into Insurance Fraud Trends' in 2013, around 35 percent of respondents estimated that claims fraud costs their company, about 5-10 percent of the claims amount, and more than 30.5 percent of the participants pegged the loss rate between 10 and 20 percent.[iii]

A Few Instances of Fraud in Insurance Claims and its Impact on the U.S. Insurance Industry

The FBI arrested 36 people in New York - including 10 doctors and three lawyers - for their alleged involvement in a $279 million auto insurance fraud

Marc Thompson, deeply in debt, torched his home for the $7.3 million in insurance money

Insurance fraud drains more than $50 billion from insurers each year and costs the average U.S. family between $400-700 in the form of increased premium, according to the FBI

---

1. FICO - Founded in 1965, FICO is a leading analytics software company that provides tools across multiple industries to manage risk, fight fraud, build more profitable customer relationships, and optimize operation

Fraud in 'No-Fault' States[2]

The U.S. is also witnessing a higher rate of Organized Group Activity (OGA)[3]. The National Insurance Crime Bureau (NICB)[4] reported a 14 percent rise in Organized Group/Ring Activity from 2,310 questionable claims (Qcs)[5] for nine months (Q1-Q3) in 2012 to 2,643 QCs for nine months (Q1-Q3) in 2013.[iv] In 2012, NICB conducted a survey to examine OGA and reviewed 13,014 Qcs for the period January 2008 to June 2012. The top five states that generated the most questionable claims were: Florida (3,530), California (2,679), Michigan (1,080), Texas (1,050) and New York (765)[v]. Looking closer, three are 'No-Fault' states (Florida, Michigan, and New York), and one, Texas, although not 'No-Fault,' has partially adopted some 'No-Fault' policies. 'No-Fault' policies put much of the burden to pay on the injured party's own insurance company, regardless of fault, and impose a strict timeline within which the claim must be accepted or rejected. Although intended to simplify and expedite the claims process, these policies make it much easier to stage accidents and defraud insurance companies. Worse, the timelines make it difficult for insurers to detect fraud fast enough, and even if they do, they are often sued for negligence in their examination of the claim.

Fraud in Personal Lines

Fraud losses in personal line, mainly led by fraudulent auto injury claims, were estimated to rise in double digits over a two-year period and reach $18.5 billion, in 2014[vi]. Worse, because of liberal rules and dishonest lawyers, who support such crimes, 'No-Fault' states reported an even higher appearance of fraud for personal injury protection (PIP) claims (Florida - 31 percent, New York – 24 percent, Massachusetts – 22 percent, and Minnesota – 22 percent)[vii].

2. States with the no-fault system of insurance, where insurers indemnify for basic damages and injured parties are paid by their own insurance company, regardless of fault

3. Any specific group made up of entities and/or individuals, who systematically and repeatedly conduct pre-planned activities for the purpose of generating fraudulent insurance schemes

4. NICB is a non-profit organization that partners with insurance companies and law enforcement to help identify, detect, and prosecute insurance criminals

5. Claims referred to NICB by member insurance companies for closer review and investigation of possible fraud

Exhibit 2

Estimated Annual Losses in P&C Lines due to Fraudulent Claims in 2014 ($ Million)[6]

| ■ Personal Lines | ■ Commercial Lines | ■ Combined Lines |

Line	Amount
Auto Liability	$8,820
Auto Physical	$5,158
Homeowners Multiple Peril	$4,484
Workers' Compensation	$3,329
Other Liability	$2,833
Commercial Multiple Peril	$2,120
Commercial Auto Liability	$1,461
All Other	$892
Medical Professional Liability	$562
Accident and Health	$552
Commercial Auto Physical	$411
Products Liability	$349
Financial Guaranty	$224
Farm owners Multiple Peril	$214
Allied Lines	$1,057
Inland Marine	$562
Fire	$547
Mortgage Guaranty	$308
Warranty	$130

Source: WNS DecisionPoint™ estimates (based on data by National Association of Insurance Commissioners (NAIC)

Vulnerability of personal lines is also evident from double-digit increase in questionable claims (QC), referred to NICB, in the last four years. The rise was mainly driven by referral reason suspicious theft of vehicles.

Organized fraud is also high in personal line insurance. As per NICB's report on Organized Group Activity, which stated 'personal automobile' as the policy type that reported the highest number of referrals (10,659 QCs

out of 13,014 QCs were reviewed during the study period).

---

6. Assuming 10 percent of the Losses Incurred and the Loss Expenses incurred during respective years

IMPACT OF FRAUD

Fraudulent Claims Skew Combined Ratio and Underwriting Profitability

Fraudulent claims directly impact Loss Ratio, thereby, reducing profitability and also negatively impacting Return on Equity (ROE). As reflected in Exhibit 3, despite a fall in Expense Ratio, an elevated Loss Ratio pulled down ROE in 2014. During the same period, a 1.8 pps (percentage points) increase in Loss Ratio also negatively impacted underwriting profits by 26 percent in 2014. Maintaining Combined Ratios below 100 is a pre-requisite for P&C insurers to post reasonable levels of profitability.
This emphasizes a strong need of loss management to control dishonest claims payout through better fraud detection techniques.
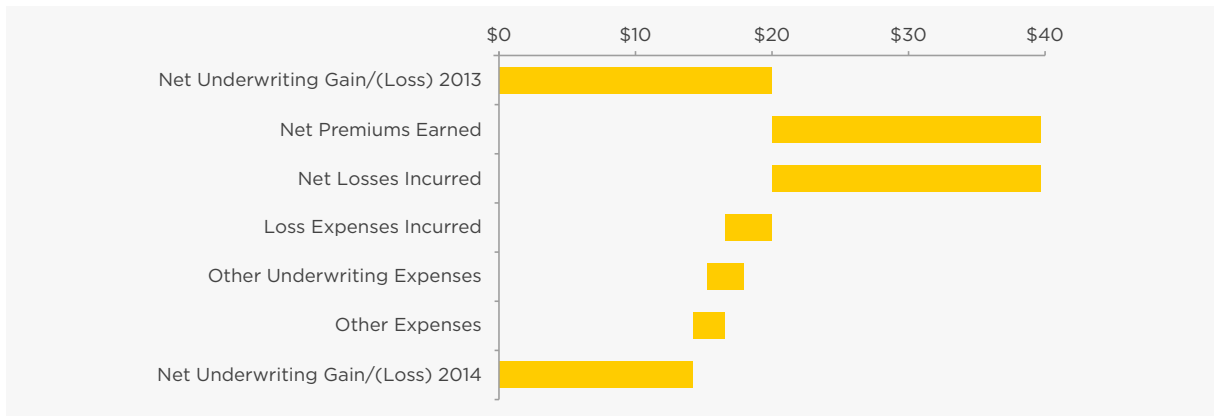

Exhibit 3

U.S. Property and Casualty Insurance – Key Financials

Source: Insurance Information Institute and NAIC

Fraud Also Impacts Insurer's Ability to Offer Competitive Premiums

Fraudulent claims add to premium costs, since insurers are compelled to pass on the cost of such claims to policyholders. According to the WNS DecisionPoint™ survey, half of the respondents felt that fraud escalates premiums by three to five percent. Nearly a quarter of the respondents reported escalation to be over five percent; while the rest mentioned it to be between one and three percent. The cost of fraud added to the premiums varies across insurance lines and states, and is much higher for 'No-Fault' states such as New York, Florida and New Jersey. These states have the highest auto premium prices, mainly caused by fake claims involving staged car accidents. Fraud is also primarily responsible for rapidly rising workers' compensation premiums, driven by false injury claims and misrepresentation of facts at the time of application.

However, given the competitive environment, increasing premiums to compensate for fraud losses is no longer feasible for the insurer. This trend, combined with low investment yield (drop of 57 pps from 3.74 percent in 2011 to 3.17 percent in 2014)[viii], has also impacted the profitability of the insurer. Given all this, insurers need to shift from traditional ways of detecting fraud and adopt advanced fraud detection and prevention techniques.

SHIFT IN FRAUD DETECTION APPROACH WITH RISE OF ANALYTICS

Traditional approach of detecting fraud is still being used by few insurers in this era of complex and sophisticated crime. Some of the traditional methods are internal audits, red flag indicators, and scoring models, as explained in the illustration below.

Exhibit 4

Traditional Fraud Detection Methods

Traditional Methods		
Internal Audit	**"Red Flag" Indicator**	**Scoring Models**
▪ Random checks on sample claims leave a room for some fraudulent claims to go undetected ▪ Lack of experience of insurance fraud professionals results in lower detection and investigation rate	▪ Rule-based indicators to detect suspicious behavior ▪ Red flags indicate the need to further investigate a claim and does not conclude the claim to be fraudulent	▪ An advancement to rule-base techniques, wherein insurers provide scores to rule-based indicators (either manual or automated) ▪ Based on fraud propensity scores, claims are classified into various segments such as high, medium and are subsequently referred to for further investigations

Source: WNS DecisionPoint™

These traditional methods primarily detect known fraud patterns using sampling techniques. Since these methods require manual intervention, there is a higher possibility of human error and longer lead times from fraud detection to the settlement of claims. Traditional approaches are also known for high false-positive rates (flagging genuine claims as fraudulent), which impact customer satisfaction. Given the competitive environment with high customer switching rates, especially for auto insurance, low customer satisfaction adversely impacts customer retention. Despite these drawbacks, some P&C insurers in the U.S. still continue to use these traditional methods as they lack the expertise and infrastructure to deploy advanced analytical techniques.

AUTOMATED AND ANALYTICS-DRIVEN FRAUD IDENTIFICATION AND INVESTIGATION

Realizing the limitations of traditional methods, many carriers have started adopting anti-fraud technology to determine the likelihood of claims fraud. As per the survey report on 'Insurance fraud detection technology' conducted by Coalition Against Insurance Fraud (CAIF) and SAS Institute, the number of respondents using anti-fraud technology grew from 65 percent in 2012 to 71 percent in 2014[ix].

Insurers are also increasingly adopting analytics to predict the occurrence of fraudulent claims (notably in the case of catastrophes, which greatly magnify the scope for fraud), and to drive innovations in detecting organized activity early in the claims cycle.

The increasing adoption is reflected in increased investments in data analytics and modeling technologies by insurers. According to a survey of 42 insurers by CAIF and SAS Institute, 25 percent planned to increase investments in anti-fraud technology between 2014 and 2016[ix]. Investments in advanced solutions such as link analysis, predictive modeling and other sophisticated data analytics are expected to increase and insurers will partner with specialist service providers to drive down fraud-related expenses. This helps insurance companies quickly and accurately determine whether a claim needs further investigation and to determine the complexity of the claim.

How Fraud Analytics Add Value at Each Stage of the Policy Life Cycle?

Fraud can be detected across the four stages of the policy life cycle as mentioned below. Fraud analytics, if deployed at various stages of the policy life cycle, enable insurers to have a comprehensive view of each policyholder, which paves the way to discover organized frauds.

Exhibit 6

Guard your Margins by Applying Advanced Fraud Analytics over Various Stages of the Policy Life Cycle

Point of Sale	First Notice of Loss (FNOL) Claims Handling	Investigation	Post Claims
Capture Precise Identity of Applicants	Validate a Larger Number of Claims in a Shorter Period of Time with Higher Accuracy	Promptly Uncover Linkage of Claimants with Fraud	Quickly Analyse Organized Frauds with Higher Accuracy
Discover the Linkages of Applicants with Fraud	Categorize Risks and Derive Fraud Propensity Scores in Near Time	Reduce Claims Investigation Costs	
Detect Abnormal Behavior Patterns of Applications		Reduce Investigation Time	

Source: WNS DecisionPoint™ Analysis
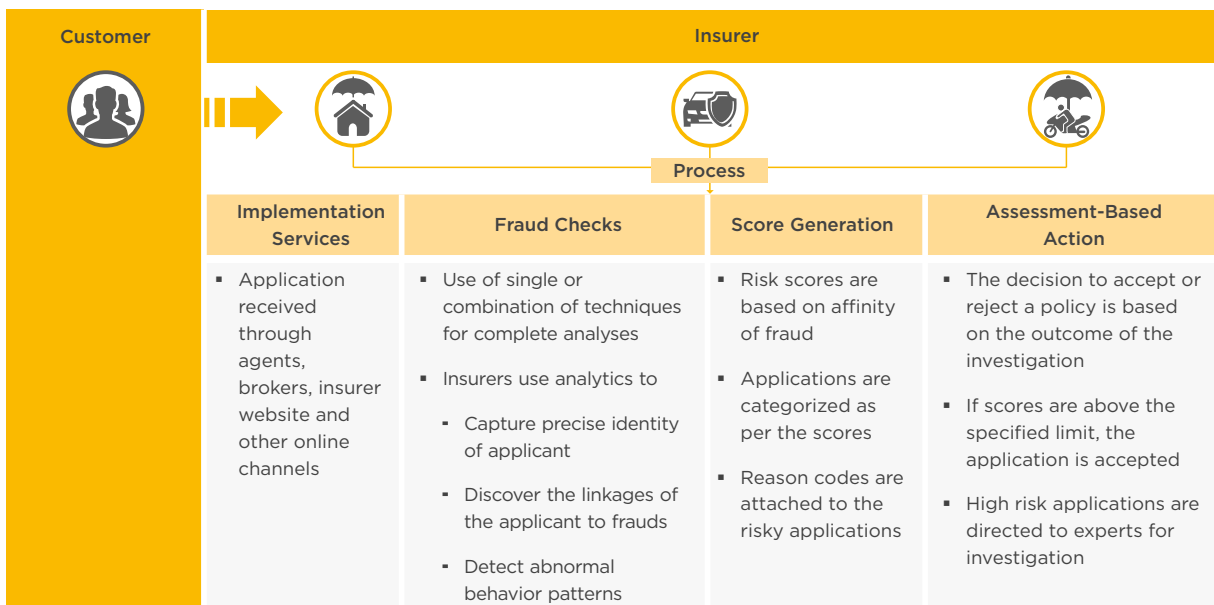

Point of Sale (POS)/Renewal Stage

Since a sizable part of claims fraud is initiated at the application stage, it is very important for insurance companies to put a check on the underwriting fraud to decrease premium leakage and avoid exposure to known fraud at the claims stage.

Exhibit 7

Fraud Detection Process at POS/Underwriting Stage

Customer	Insurer			
	Process			
	Implementation Services	Fraud Checks	Score Generation	Assessment-Based Action

	▪ Application received through agents, brokers, insurer website and other online channels	▪ Use of single or combination of techniques for complete analyses
		
		▪ Insurers use analytics to
		
		  ▪ Capture precise identity of applicant
		
		  ▪ Discover the linkages of the applicant to frauds
		
		  ▪ Detect abnormal behavior patterns
			▪ Risk scores are based on affinity of fraud
			
			▪ Applications are categorized as per the scores
			
			▪ Reason codes are attached to the risky applications
				▪ The decision to accept or reject a policy is based on the outcome of the investigation
				
				▪ If scores are above the specified limit, the application is accepted
				
				▪ High risk applications are directed to experts for investigation

**Source:** WNS DecisionPoint™ Analysis

Apart from the traditional Red Flag indicator method, many insurers are using a combination of business rules and analytics to tackle underwriting fraud. According to the WNS DecisionPoint™ survey, all respondents deployed predictive modeling techniques at the underwriting stage to enhance understanding of current and future insured risks, as seen in Exhibit 8. As a result, insurers were able to develop premiums that accurately reflected the relative risk characteristics of the pool of underlying policyholders.

Exhibit 8

Types of Fraud Analytics Currently Used by P&C Insurers at the Underwriting Stage

Category	Percentage
Social Media Analytics	25%
Social Network Analysis/Link Analysis	25%
Geographic Data Mapping	25%
Text Mining	25%
Data Visualization	50%
Automated Red Flag	70%
Predictive Modeling	100%

Source: WNS DecisionPoint™ Survey

After implementing analytics at the point of sale stage, most of the carriers were able to promptly detect fraudulent policies and exercise better control over business rules indicators. This section of insurers also experienced lower claims volumes and additional benefits as shown below.

Exhibit 9

Benefits Realised from Using Fraud Analytics at the Underwriting Stage

Category	Percentage
Lower % of the Policies that Get Cancelled	25%
Higher Detection Rate of Suspicious Policy	50%
Decline in Average Time to Identify an Issue in a Policy	50%
Lower % of Policies that Registered Claims within 100 Days of Sale	50%
Reduced Premium Leakage	50%
Lower Average Claims Value	75%

Claims Stage

At the FNOL stage, the role of claims handler is very important as they are responsible for processing and investigating insurance claims relating to customers' policies.

Thus, the inability of claims handlers to accurately notice doubtful patterns results in fake claims getting paid. The chart below illustrates important role of

analytics in the fraud detection process at the claims stage, investigation stage, and post-claims stage.

Exhibit 10

Fraud Detection Process at Claims Stage, Investigation Stage, and Post-Claims Stage

FNOL	Claims Handler	Adjuster	Investigator	Investigation-Post Claim Settlement
▪ After loss of the property/vehicle is reported by policy holder, FNOL agent gathers details pertaining to the event and subsequent loss ▪ FNOL agent uploads the information gathered in the above stage in the company's system which can be referred to by claims handler and adjusters ▪ FNOL agent then initiates claims process by informing claims handler	▪ Claims handler identifies suspicious claims by applying rule based techniques ▪ Verifies claims data against companies' records and industry databases ▪ Assigns scores to claims based on fraud possibility ▪ Directs high-risk claims to more experienced claims handlers or to SIUs ▪ Informs an adjuster for futher action	▪ Adjuster physically assesses the damages, the loss value and estimates the claims amount ▪ Uploads the findings gathered at this stage into the systems which is then referred to by investigators	▪ Investigator further examines the referrals highlighted by claims handler ▪ Refers to various databases and uses a mix of statistical and traditional techniques to identify the fake claims ▪ Initiates further action based on the outcome of the investigation	▪ Special teams examine large claims data using data mining and multi-variate analytics techniques ▪ Post claims analyses enable investigators to reveal fake claims that are not evident in smaller data sets

Source: WNS DecisionPoint™ Analysis

Most claims handlers assess claims using a set of specified indicators and then verify submitted details with the data generated from internal systems of record (log book, policy data, and customer

records) and external data sources (NICB, Insurance Services Office (ISO)[7] Claims Search, among others). It is very important to provide accurate and recent information/data to claims handlers

as analysis of incorrect or outdated information results in undisclosed dishonest claims and also generates high false positive rate, which overburdens the Special Investigative Unit (SIU).

---

7. ISO provides information about property/casualty insurance risk for a broad spectrum of commercial and personal lines of insurance

In order to validate a larger number of claims in a shorter period of time with higher accuracy, claim handlers are required to use sophisticated analytics. This, in turn, results in the identification of low-fraud incidence events (with probability as low as 0.001 percent). Some analytics techniques, such as predictive modeling, enable insurers to categorize risks and derive fraud propensity scores in real time, which helps claims handlers adjust their line of questioning and route suspicious claims to investigators. Analytics solutions, such as reporting and visualizations of data patterns, also help insurers easily understand the impact of ongoing fraud analysis on their business. As per the survey conducted by WNS DecisionPoint™, insurers using analytics reported higher benefits compared to the insurers, who are using traditional methods or automated indicators (see Exhibit 11).

Exhibit 11

Benefits Realized from Usage of Analytics to Detect Fraud at Claims Handling Stage

X-axis: No. of Respondents (in%) — 0% to 100%
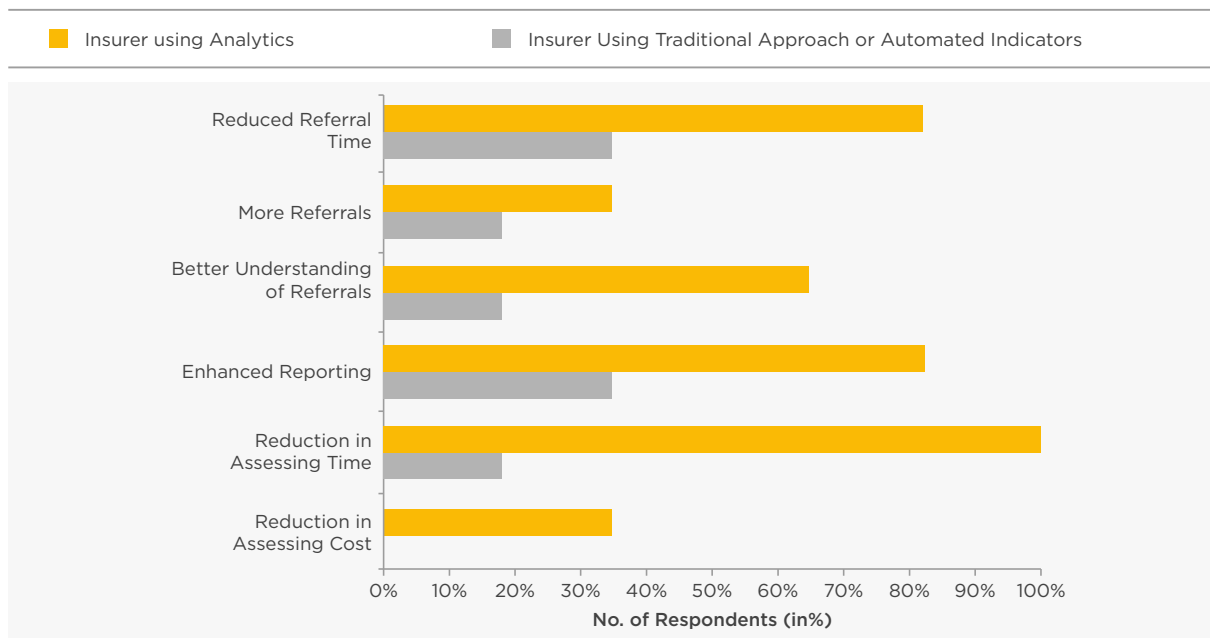

Source: WNS DecisionPoint™ Survey

Investigation Stage

Within the claims life cycle, analytics is largely used at the investigation stage. At this stage, investigators scrutinize each claim referred to by claims handlers. They compare claims' data against various data sources (such as policy information, claim history, medical reports, NICB, ISO, among others) to check the veracity of the information provided by claimant. Analytics play an important role in collecting, consolidating and integrating scattered data from various data sources. Techniques such as social network analytics enable investigators to quickly uncover linkage of claimants with fraudulent activities, thereby, decreasing the amount of time taken to expose hidden relationships among entities and potential fraud. However, owing to lack of in-house expertise, extensible and scalable information foundation and technology systems, adoption of analytics by

the U.S. based P&C insurers is low and they usually rely on automated red flags and business rules to determine fake claims. Further, only predictive analytics is being deployed at investigation stage to improve fraud detection and speed up claims processing, indicating underuse of other solutions, as shown in the chart below.

Exhibit 12

Techniques Currently Employed by Insurers to Detect and Investigate Fraudulent Claims

Post-Claims Stage

Application of fraud analytics at the post-claims stage is in a nascent phase and is mostly deployed by players with P&C revenues over $5 billion. Few insurers employ a special team within their SIU, who specially look into claims after their settlement. This team analyzes enormous volumes of claims data to determine patterns of fraud, which surface gradually and are difficult to trace in individual claims investigations. This is more common in the No-fault States, where insurers are required to make faster settlements and do not have enough time to scrutinize claims thoroughly.

At this stage, the SIU analysts compare large volumes of claims data using multiple techniques and tools (such as combinations of business rules, automated red flags, predictive modeling, and text mining, among others) to uncover unrevealed inter-relationships between claims and other entities[8] involved in such activities. These insights enable insurers to discover organized fraud, and also to continuously improve the rules and models operating at the POS, FNOL, and Investigation stages.

8. Claimant, locations where damage happened, witnesses of accidents, and auto body shops, among others

BIG DATA FRAUD ANALYTICS

Fraud analytics has evolved from building models and providing fraud scores to policies and claims, to enabling real-time fraud detection by efficiently and effectively processing the deluge of structured and unstructured data that is available within and outside the company.

Insurers mostly analyze structured and unstructured data, which represents just 15-20 percent of the total data that is generated by insurance organizations and is mostly historical in nature[x]. It is to be noted that analysis is based on historical data tends to lose its predictive power beyond a certain point.

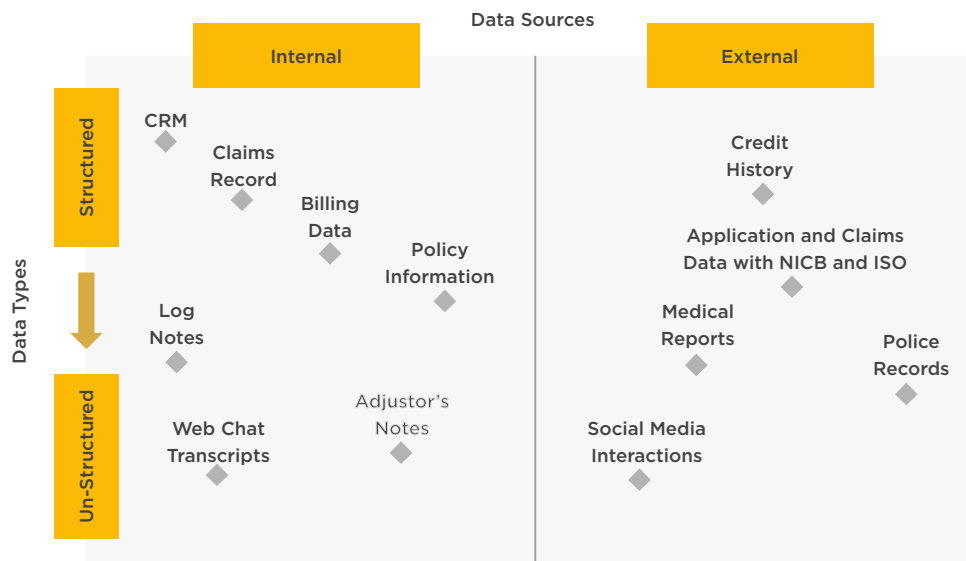

Exhibit 13

Types of Data Analysed for Fraud Detection by Insurers Across Stages
Source: WNS DecisionPoint™ Survey

In the current environment, where fraud rings adopt sophisticated techniques, real-time data availability is crucial to increase accuracy. Analysis of internal and external unstructured data provides a great opportunity to uncover complex fraudulent activities, which are difficult to trace through analysis of the structured data. For instance:

- Scanning through social media interactions of a claimant may reveal his visit to a bar before his car accident

- Applying analytics on claimant's social network data may reveal his connection with entities who are/were involved in fraudulent activities

- Log notes and web interactions can confirm claimant's urgency for claim settlement, adjustor's notes may point out inflated vehicle repairs

Such a multi-pronged, coordinated approach to fraud can be used for comprehensive risk shrinkage by altering fraud detection

policies/rules at underwriting stage and also save on promotional costs by avoiding marketing to such 'potential high-risk' prospective customers. Apart from disclosing hidden fraudulent activities, unstructured data analysis also enables insurers realize many benefits in terms of efficient processes and reduced costs.

Exhibit 14

Benefits of Analysing Unstructured Data as Reported by the U.S. P&C Insurers
Source: WNS DecisionPoint™ Survey

Benefits accrued from the assessment and evaluation of unstructured data have encouraged insurers to invest more on tools and techniques to examine Big Data (notably social media posts) to flag claims for closer inspection, priority handling and settlement. However, use of unstructured Big Data such as

e-mails, blogs, web interaction, audio/video, and images, is still at a nascent stage. Predictive analysis, on the other hand, uses a combination of rules, modeling, text mining, database searches and exception reporting as mentioned in the charts below.

Exhibit 15

Extent of Usage of Unstructured Big Data in Next 24 Months
Source: WNS DecisionPoint™ Survey

Big data is scattered within and outside the organization and is in an unstructured form, which makes it very difficult for an insurer to gain meaningful insights. Insurers are required to possess robust data management capabilities to be able to cleanse and integrate the external data with internal data and obtain a complete view of the policy holder, claimant, and his/her actions. Thus, very few insurers are able to analyze unstructured data owing to technology inadequacies and a lack of in-house expertise in this area.

Building an Environment to Support the Use of Big Data Analytics

- The data (structured, semi-structured and unstructured) collected from various sources are fed into the data collection tool.

- The data is then cleansed, to be loaded into a data warehouse. The semi-structured data, as sourced from ISO and NICA reports, is reconstructed into the structure appropriate for running predictive models. Unstructured data sourced from log notes, e-mails, adjuster's notes, among others, may not be in English and may contain fragments of sentences, acronyms, copy and pasted e-mails, images, typos, misspellings, etc. This data is also transformed and loaded into the data warehouse.

- The analytics team uses the information stored in the data warehouse and combines that information into analytics models to generate fraud scores based on multiple factors. The information used includes previous sentences, associations with other people with past fraud cases, multiple rejected claims, and modifications to personal information.

- Techniques such as predictive modeling, social media analysis, and social network analysis, are integrated into the fraud identification modeling process, which further modifies the scores based on the output from these techniques.

- The alerts generated by analytics models are further investigated and evidence collected from this model is added to the existing system to further build the case.

Role of Big Data Analytics at Various Stages of the Policy Lifecycle

It is very crucial for insurers to implement Big Data analytics at all three stages of the policy life cycle to develop an end-to-end, comprehensive fraud management programme.

Point of Sale or Underwriting stage	Claims Stage	
Prior to the Submission of a Claim	**FNOL/Claims Handling Stage**	**Investigation Stage and Post-claims Settlement**
• Examines policies for identifying theft and recognizing deceitful patterns • Provides real-time insights to determine and validate the true identity of policy applicants • Discovers complex relationships and linkages with criminal activities	• Determines discrepancies much faster in the claims lifecycle through a combination of traditional rule-based techniques and advanced analytics, such as social media analytics and predictive modeling • Reduces the average cycle time for legitimate claims	• Scrutinizes claims in detail and helps investigator to collect possible fraud evidence • Quickly incorporates claim data related to all entities involved from various unstructured sources using text and data mining techniques to establish relationships among various parties involved in a claim • Creates leads and clues (through use of link analysis and social network analysis) to prepare evidence for fraudulent claims • Promptly alters controls, based on emerging trends and new fraud patterns

Benefits Generated by Insurers who Deployed Big Data Analytics

Although challenging, analyzing Big Data enables insurers to understand unknown correlations much earlier in the policy life cycle and to develop a deeper understanding of emerging suspicious patterns or risks. Insurers adopting Big Data analytics reported 40 percent improvement in the average referral time, 50 percent more average referrals, 2.5x reduction in average investigation time and 1.4x lower average investigation costs compared to insurers, who have not deployed such sophisticated statistical techniques (see Exhibit 16).

Exhibit 16

Benefits Reported by Insurers at Claims Handling Stage

- 🟧 Low (deployed Big Data Analytics)
- ⬜ High (Deployed Big Data Analytics)
- 🔺 Average (deployed Big Data Analytics)
- 🔶 Average (not deployed Big Data Analytics)
Source: WNS DecisionPoint™ Survey

Adoption of Big Data analytics at the investigation stage also enables insurer to gain similar benefits in terms of cost and time. The average investigation cost of insurers, who use Big Data analytics, was 67 percent lower, and the average time per claim investigation was 2x shorter, compared to the other insurers. Insurers also reported other benefits as shown in the graph below.

Exhibit 17

Benefits Generated at Investigation Stage

■ % of Insurers Using Big Data Analytics   ■ % of Insurers Using Traditional Approach or Automated Indicators or Analytics
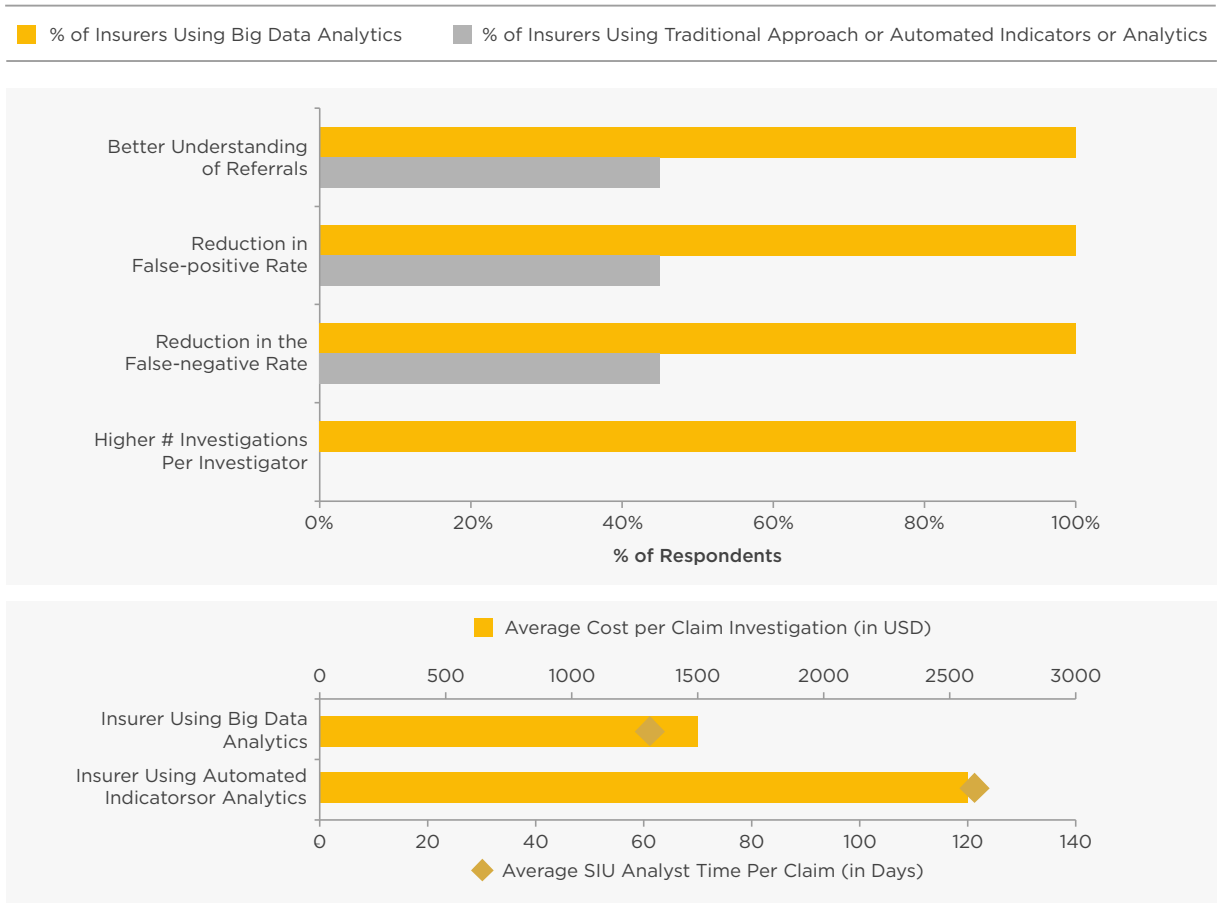

Source: WNS DecisionPoint™ Survey

Low Adoption of Big Data Analytics

The adoption rate of Big Data analytics is very low across the policy life cycle. This is especially true at the underwriting stage, where only one-fourth of respondents have only invested in Big Data analytics and are still at a knowledge gathering stage.

At the claims handling stage, although 73 percent of the respondents have invested in Big Data analytics, complete deployment is accomplished by only a few of them, and most insurers are either in the pilot stage or at a knowledge gathering stage (see Exhibit 18). Insurers are reluctant to invest in such projects, as the practical challenge of defining ROI from such investments remains. They also face capital crunch for funding such projects and have infrastructure constraints to support Big Data application requirements, tool capabilities, and best practices for implementation. Adoption of Big Data analytics at the investigation stage is moderate with near to 50 percent deployment rate.

Exhibit 18

Percentage of Respondents Currently Using Big Data Analytics to Detect Fraud at the FNOL Stage

Legend: ■ Invested in Big Data Analytics ■ Not Invested in Big Data Analytics

- 73% | 27%
- 25% | 38% | 38% — Stage of Big Data Adoption during FNOL Stage

Axis: 0 20 40 60 80 100

Legend: ■ Knowledge Gathering ■ Piloting and Experimenting ■ Deployed
Source: WNS DecisionPoint™ Survey

However, increasing confidence in Big Data analytics is driving a large number of insurers to invest in utilizing new sources of data that extend beyond traditional and internal sources. As per WNS DecisionPoint™ survey, around 33 percent of the underwriters, who have not leveraged Big Data techniques, are planning to make such investments in the next year and the rest, within a period of two years. Most of the claims handlers and investigators, who have not invested, are also planning to deploy Big Data technologies within two years.
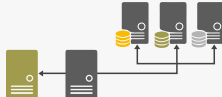

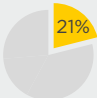

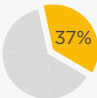

Challenges in Adopting Big Data Analytics

The challenges across the various stages of Big Data implementation need to be clearly understood and addressed to ensure the maximum chance of success. Big Data adoption is broken into four phases: Planning, Knowledge Gathering, Pilot, and Full-scale Deployment.

Exhibit 19

Adoption Phases of Big Data Analytics

Adoption Phases	Planning	Knowledge Gathering	Pilot	Deployment
Key Activities	▪ Sets plans to guide project teams throughout the adoption phases ▪ Determines the investments and anticipated benefits from such projects	▪ Takes into account existing and untapped in-house sources and assesses the requirement of additional data types	▪ Runs pilots to determine the feasibility of such projects and its impact on organizational goals ▪ Analyses benefits realized and runs pilots again in case projects fails to produce expected results	▪ Ensures that departments exposed to Big Data analytics, have understood the associated governance and risk management practices ▪ Ensures that organizational requirements are in place such as integration of the siloed data; additional resources to handle higher work volumes; added capacity to store, maintain and manage such data
% of Respondets at Each Stage	21%	37%	16%	26%
Key Challenges	▪ No easy way to determine the ROI of Big Data investments	▪ Technology and infrastructure requirements to acquire, host and analytically process the vast amount of data gathered ▪ Risk and governance issues(security, privacy, data integrity)	▪ Making the infrastructure and applications production-ready in operations environment ▪ Management of large referral volumes generated by analytics usage	▪ Capital allocation for big-data-related initiatives ▪ Higher levels of technology support ▪ Integrating multiple data sources

Insurers, at different phases in the Big Data adoption, face different problems (as stated in the above diagram) and require appropriate solutions, which will not only enable them to reach the deployment phase sooner, but also maintain and enhance the processes, thereafter.

- **Insurers at planning phase:**
  At this stage, while insurers face many issues, their main concern is determining the decision-support value of Big Data, as reported by 75 percent of the respondents. Nearly a quarter of the respondents struggle to understand the definition and use of Big Data and the analytics capabilities required to enhance decision-making speed and effectiveness. These insurers should:

  - Ensure that Big Data strategies are aligned with business objectives

  - Conduct stakeholder communication/education sessions to articulate the business value of Big Data in improving the fraud management processes. Some of the benefits accrued to the insurer include increased true positive referral rate, early forewarning of suspicious behavior, reduced average cost of investigation per claim, and shortened claim investigation time by SIU analyst, among others

- **Insurers at a knowledge gathering phase should:**

  - Explore the volume and variety of unused data within and outside the organization,

optimize the usage of internal and external data and accordingly, assess the organizational, information management and technological changes needed to embrace Big Data

- Understand the requirements of tools and techniques to manage and glean relevant insights from big data sources, application of statistical and predictive analysis techniques, best practices and organizational change readiness

- Make sure that all data points, captured from various internal and external sources, are integrated into the company's system to provide a unified view of policies/claims across the underwriting department, the claims department and the investigation department. If internal IT systems are fragmented and not geared to handle Big Data, the project will fail to produce desired outcomes

- **At the pilot stage, insurers should:**

  - Ensure that various departments are ready for the pilot or proof of concept run – especially the investigation department, as they are likely to experience higher work volumes

  - Ensure close coordination between the various departments including SIU, claims, underwriting and IT to jointly determine Big Data implementation blueprint

- Classify the business units as owners and implementers to provide clarity regarding roles and responsibilities of each participant

- Evaluate the gap between estimated and actual benefits derived from usage of Big Data analytics

- Document lessons learned from implementation failures and use that during the planning and design of the next pilot

- **Insurers, who have already deployed Big Data analytics should:**

  - Train SIU analyst and investigator resources to institutionalize the usage of Big Data analytics

  - Modify or update red flag rules and reframe fraud detection and prevention strategies, whenever a new fraudulent pattern is discovered

  - Continue to explore the untapped data existing within the organization and external data to promote higher and accurate fraud detection and prevention

Insurers, who are thinking of adopting these techniques and the underpinning technologies in the near future, can consider enlisting the services of a specialist analytics service provider in order to share the significant investments required in such projects and acquire the right skills and domain expertise in the shortest period of time.

THE KEYS TO SUCCESSFUL BIG DATA ADOPTION

For robust fraud management practices, a comprehensive framework is required, which scans all possible areas of fraud in the policy life cycle, in a unified manner. Below are the emerging best practices to successfully operationalize Big Data analytics.

- Build a dedicated fraud management team to coordinate fraud detection processes of various departments – underwriting, claims, and SIU.

- Evaluate prevailing fraud detection system(s) and identify gaps, if the system is not aligned with the organizational objectives.

- Recognize the skill sets required to implement Big Data analytics and accordingly, decide whether to build the analytics solutions in-house or partner with external vendors. If the decision is to use an external vendor, evaluate different vendors to find the solution that best aligns with the company's requirements.

- Ensure all the data points from the various departments involved in fraud detection process are integrated in a unified policy/claim view.

- Reframe the prevailing business rules by leveraging domain expertise and set realistic threshold values for different anomalies.

- Use a combination of different detection techniques to improve the efficiency of fraud management process. For instance, business rules and anomalies detection can be applied to all claims to identify discrepancies in data or to find those claims that exceed the anomaly threshold limit. The screened claims then can be filtered by running predictive models which assign a fraud propensity score to each claim.

- Integrate social media analytics and social network analytics with predictive modeling to uncover evidence of fraudulent activities.

- Continue to explore untapped data and integrate such data points into existing fraud detection system.

Since their creation, P&C insurance companies have been battling fraudulent policies and claims. Currently, this fraud can increase claims expenses by up to a staggering 20 percent. As schemes for committing fraud proliferate, traditional fraud detection techniques are becoming less and less effective. Automated rules have helped, but they are inefficient and ultimately not the best available solutions. The future is clear. Big Data analytics offers underwriters, claims handlers, and investigators an advanced and statistically reliable solution to revolutionize their fraud management processes. Adoption of Big Data analytics may be challenging, but the end result is worth it.

About DecisionPoint

Making key decisions that improve business performance requires more than simple insights. It takes deep data discovery and a keen problem solving approach to think beyond the obvious. As a business leader, you ought to have access to information most relevant to you that helps you anticipate potential business headwinds and craft strategies which can turn challenges into opportunities finally leading to favorable business outcomes.

WNS DecisionPoint™, a one-of-its kind thought leadership platform tracks industry segments served by WNS and presents thought-provoking original perspectives based on rigorous data analysis and custom research studies. Coupling empirical data analysis with practical ideas around the application of analytics, disruptive technologies, next-gen customer experience, process transformation and business model innovation; we aim to arm you with decision support frameworks based on points of fact. Drawing on our experience of working with 200+ clients around the world in key industry verticals, and knowledge collaboration with carefully selected partners, including Knowledge@Wharton, each research asset draws on "points of fact" to come up with actionable insights which enables 'bringing the future forward'.
